## FIT2014 Tutorial 2 Sets, Games, Proofs

### ASSESSED PREP

You must provide a self-reflection question at the start of your tutorial (for on-campus classes), or submit it at the start of your tutorial (for online classes).

#### 1. (mostly from FIT2014 Final Exam, 2018)

The predicate  $\text{supervised}(X, Y)$  has two arguments, both of which are people. The meaning of  $\text{supervised}(X, Y)$  is that person  $X$  supervised the PhD of person  $Y$ .

Express each of the following three sentences in predicate logic.

(a) Alonzo Church was the PhD supervisor of Alan Turing.

(b) No person supervised their own PhD.

(c) Not every PhD supervisor had a PhD supervisor.

*Note.* This one must be written as an *existential* statement.

(d) Alan Turing supervised only one person's PhD.

2. This question is about the game *Noughts-and-Crosses* (known as *Tic-Tac-Toe* in the US). This game is played using a  $3 \times 3$  grid, usually drawn in the manner of Figure 1(a). Two players, *Crosses* and *Noughts*, each take turns to place  $X$  and  $O$ , respectively, in one cell of the grid. Once a cell is occupied by one player, its entry cannot be changed, and neither player can play there again. A player wins when they have three of their symbols in a line, horizontally, vertically, or diagonally, there being eight possible lines altogether; when that happens, the game stops. If all cells are occupied (five by Crosses and four by Noughts) and none of the eight three-cell lines have three identical symbols, then the game stops and is a Draw. (For simplicity, we forbid resignations and agreed draws.)

(a)

(b)

(c)

Figure 1: Some positions in Noughts-and-Crosses

The variable  $P$  always stands for a position in Noughts-and-Crosses, which represents the state of the array after the players have played some number of moves. A position thus corresponds to a  $3 \times 3$  array with some subset of the cells occupied, in which the number of Crosses either equals, or

# 程序代写代做 CS编程辅导

exceeds by one, the number of Noughts. In the former case, then the next player to move must be Crosses; in the latter case, the next player to move must be Noughts. The diagram in Figure 1(a) shows the position before anyone has moved; the next player to move is Crosses. The diagram in Figure 1(b) shows a position where Crosses has had three turns and Noughts has had two turns; the next player

A move can be specified by giving the player whose turn it is and specifying the cell into which they place their symbol. For example, if the position of Figure 1(b), the move “Noughts: centre cell” gives the position

A *winning move* is a move that wins immediately, i.e., that completes the first line of three identical symbols.

We use the following predicates and function:

- The predicate  $\text{CrossesWins}(P)$  is True if, in position  $P$ , there is a line of three Crosses and no line of three Noughts.
- The predicate  $\text{NoughtsWins}(P)$  is True if, in position  $P$ , there is a line of three Noughts and no line of three Crosses.
- The predicate  $\text{CrossesToMove}(P)$  is True if, in position  $P$ , it is the turn of Crosses to move (in other words, the numbers of Crosses and Noughts are equal, and no-one has won yet).
- The predicate  $\text{NoughtsToMove}(P)$  is True if, in position  $P$ , it is the turn of Noughts to move (in other words, the number of Crosses is one greater than the number of Noughts, and no-one has won yet).
- The function  $\text{ResultingPosition}(P, X_1, X_2, \dots, X_k)$  returns the position produced by starting with position  $P$  and then playing moves  $X_1, X_2, \dots, X_k$  (where  $1 \leq k \leq 9$ ). For example, if  $P$  denotes the position in Figure 1(b), then  $\text{ResultingPosition}(P, \text{“Noughts: centre cell”})$  gives the position in Figure 1(c). If a move  $X_i$  is illegal — because it is out of turn, or in a cell that is already occupied — then it has no effect and leaves the position unchanged.

Using quantifiers and the variables, predicates and function described above, write statements in predicate logic with each of the following meanings.

- Crosses has a winning move in position  $P$ .
- Noughts has a winning move in position  $P$ .
- For each of the statements you wrote for (a) and (b), determine whether the statement is True or False when  $P$  is the following position.

		X
	O	
X	X	O

By analogy with the definition of “winning move” given above, we could define a *losing move* to be a move that gives a position that is a win for the opponent, i.e., where there is a line of three of the opponent’s symbols that did not exist in the game before. In Noughts-and-Crosses, this never happens. (Why?)

# 程序代写代做 CS编程辅导

- (d) Write a predicate logic statement to say that losing moves are impossible.

Now write predicate logic statements with each of the following meanings, where again  $P$  can be any Noughts-and-Crosses position, and  $P_0$  the initial position (when the  $3 \times 3$  grid is empty: see Figure 1(a)).

- (e) Crosses has a strategy to win within three moves from position  $P$  (where the three moves are one by Noughts, or one by Crosses, or one by Noughts, or one by Crosses).

- (f) Crosses does not have a winning strategy within three moves from position  $P$ .  
For this question, you may assume that logical negation occurs immediately in front of any quantifier.

- (g) Crosses has a winning strategy from the initial position  $P_0$ .

- (h) Noughts has a winning strategy from the initial position  $P_0$ .

- (i) With best possible play from both sides from the initial position  $P_0$ , the game ends in a Draw.

- (j) It is possible for Noughts to win from the initial position  $P_0$ .

3. A language  $L$  is called **hereditary** if it has the following property:

For every nonempty string  $x$  in  $L$ , there is a character in  $x$  which can be deleted from  $x$  to give another string in  $L$ .

*Prove by contradiction* that every nonempty hereditary language contains the empty string.

4. Prove the following statement, by mathematical induction:

(\*) The sum of the first  $k$  odd numbers equals  $k^2$ .

- (a) First, give a simple expression for the  $k$ -th odd number.  
(b) Inductive basis: now prove the statement (\*) for  $k = 1$ .

**Assume** the statement (\*) true for a specific value  $k$ . This is our **Inductive Hypothesis**.

- (c) Express the sum of the first  $k + 1$  odd numbers ...

$$1 + 3 + \dots + ((k + 1)\text{-th odd number})$$

... in terms of the sum of the first  $k$  odd numbers, plus something else.

- (d) Use the inductive hypothesis to replace the sum of the first  $k$  odd numbers by something else.

- (e) Now simplify your expression. What do you notice?

(f) When drawing your final conclusion, don't forget to briefly state that you are using the Principle of Mathematical Induction!

# 程序代写代做 CS编程辅导

5. Prove, by induction on  $n$ , that for all  $n \geq 1$ , every tree on  $n$  vertices has  $n - 1$  edges.

Use the fact that every tree has a leaf, except for the trivial tree with one vertex and no edge. But it's also interesting to try to

6. (a) Prove, by induction, that for all  $n \geq 3$ ,  
$$\leq (n - 1)^n.$$

(b) [Challenge] Can you use a similar argument to show  $\leq (n - 2)^n$ ? What assumptions do you need to make about  $n$ ? How far can you push this: what if 2 is replaced by a larger number? What is the best upper bound of the form  $f(n)^n$  that you can find, where  $f(n)$  is some function of  $n$ ?

### Supplementary exercises

7. Let  $P_n$  be the proposition  $x_1 \wedge x_2 \wedge \dots \wedge x_n$ . Note that  $P_1$  consists just of  $x_1$ , and  $P_n$  is equivalent to  $P_{n-1} \wedge x_n$ .

Prove by induction on  $n$  that, if  $x_1 = \text{F}$ , then  $P_n$  is False.

8. This question is based on Lab 0, Section 8, Exercise 1.

Let *program* be any program that can be run in Linux and produces standard output. Suppose we do *program* | **wc** as above, followed by a sequence of further applications of | **wc**.

```
$ program | wc
```

```
...
```

```
$ program | wc | wc
```

```
...
```

```
$ program | wc | wc | wc
```

```
...
```

```
⋮
```

(a) Determine how many pipes are required before the output ceases to change, and what that output will be.

(b) Prove by induction that, whatever *program* is (as long as it produces some standard output), continued application of | **wc** eventually produces this same fixed output.

This is probably best done by proving, by induction on  $n$ , that if | **wc** is applied repeatedly to a file of  $\leq n$  characters, it will eventually produce the fixed output you found in part (a).
